

ASSIGNMENT NO.1.

Aim :- To create ADT that implement the "set" concept.

- a. Add (newElement) -Place a value into the set
- b. Remove (element)
- c. Contains (element) Return true if element is in collection
- d. Size () Return number of values in collection
- e. Intersection of two sets
- f. Union of two sets
- g. Difference between two sets h.Subset .

Objective:- To study the different set operations.

Theory:-

Sets are a type of abstract data type that allows you to store a list of non-repeated values. Their name derives from the mathematical concept of finite sets.

Unlike an array, sets are unordered and unindexed. You can think about sets as a room full of people you know. They can move around the room, changing order, without altering the set of people in that room. Plus, there are no duplicate people (unless you know someone who has cloned themselves). These are the two properties of a set: the data is unordered and it is not duplicated.

Algorithm :

1. Define to array to performed the set operation .
2. Then performed add function to add element in set.
3. also performed remove function.
4. Return the size of array to get number of element in set.
5. Return element which is not common in both array
6. Merge the two array.

Program Code:-

```
#include <iostream>
```

```
using namespace std;
```

```
const int MAX=50;

template<class T>

class SET

{
    T data[MAX];

    int n;

    public:

    SET()

    {
        n=-1;
    }

    bool insert(T);

    bool remove(T);

    bool contains(T);

    int size();

    void print();

    void input(int num);

    SET unionS(SET,SET);

    SET intersection(SET,SET);

    SET difference(SET,SET);

};

template<class T>

void SET<T>::input(int num)
```

```

{
    T element;

    for(int i=0;i<num;i++)
    {
        cout<<"\nEnter Element: "<<i+1;

        cin>>element;

        insert(element);
    }
}

template<class T>
void SET<T>::print()
{
    for(int i=0;i<=n;i++)
        cout<<" "<<data[i];
}

Conclusion:- Thus, we have studied different operations on set ADT.

ASSIGNMENT 2

Aim : Construct a threaded binary search tree by inserting values in the given order and traverse it in inorder traversal using threads.

Objective : To understand the concept of binary threading and to understand insertion and inorder traversal on threaded binary tree.

Theory:

Threaded binary tree : A binary tree is *threaded* by making all right child pointers that would normally be null point to the inorder successor of the node (if it exists), and all left child pointers that would normally be null point to the inorder predecessor of the node.

There are two types of threaded binary trees.

Single Threaded: Where a NULL right pointers is made to point to the inorder successor (if successor exists)

Double Threaded: Where both left and right NULL pointers are made to point to inorder predecessor and inorder successor respectively. The predecessor threads are useful for reverse inorder traversal and postorder traversal.

The threads are also useful for fast accessing ancestors of a node.

Following diagram shows an example Single Threaded Binary Tree. The dotted lines represent threads.

Algorithm :

1. Define required structure for threaded binary tree.

```

struct Node
{
    struct Node *left, *right;
    int info;
}
  
```

```
// True if left pointer points to predecessor
// in Inorder Traversal
boolean lthread;

// True if right pointer points to successor
// in Inorder Traversal
boolean rthread;
};
```

2. To perform insertion 3 cases we need to understand

Case 1: Insertion in empty tree

Both left and right pointers of tmp will be set to NULL and new node becomes the root.

```
root = tmp;
tmp -> left = NULL;
tmp -> right = NULL;
```

Case 2: When new node inserted as the left child

After inserting the node at its proper place we have to make its left and right threads points to inorder predecessor and successor respectively. The node which was [inorder successor](#). So the left and right threads of the new node will be-

```
tmp -> left = par -> left;
tmp -> right = par;
```

Before insertion, the left pointer of parent was a thread, but after insertion it will be a link pointing to the new node.

```
par -> lthread = false;
par -> left = tmp;
```

Case 3: When new node is inserted as the right child

The parent of tmp is its inorder predecessor. The node which was inorder successor of the parent is now the inorder successor of this node tmp. So the left and right threads of the new node will be-

```
tmp -> left = par;
tmp -> right = par -> right;
```

Before insertion, the right pointer of parent was a thread, but after insertion it will be a link pointing to the new node.

```
par -> rthread = false;  
par -> right = tmp;
```

Code:

```
#include<iostream>  
using namespace std;  
  
class ttree  
{  
    private:  
        struct thtree  
        {  
            int left;  
            thtree *leftchild;  
            int data;  
            thtree *rightchild;  
            int right;  
        }*th_head;  
  
    public:  
        ttree();  
        void insert(int num);  
        void inorder();  
  
};
```

```
ttree::ttree()
{
    th_head=NULL;
}
void ttree::insert(int num)
{

    thtree *head=th_head,*p,*z;

    z=new thtree;
    z->left=true;
    z->data=num;
    z->right=true;

    if(th_head==NULL)
    {
        head=new thtree;
        head->left=false;
        head->leftchild=z;
        head->data=-9999;
        head->rightchild=head;
        head->right=false;

        th_head=head;
        z->leftchild=head;
        z->rightchild=head;

    }
    else
    {
        p=head->leftchild;
        while(p!=head)
        {
            if(p->data > num)
            {
                if(p->left!=true)
                p=p->leftchild;
                else
                {

```

```

        z->leftchild=p->leftchild;
        p->leftchild=z;

        p->left=false;
        z->right=true;
        z->rightchild=p;
        return;
    }
}
else
{
    if(p->data < num)
    {
        if(p->right!=true)
        p=p->rightchild;
        else
        {
            z->rightchild=p->rightchild;
            p->rightchild=z;

            p->right=false;
            z->left=true;
            z->leftchild=p;
            return;
        }
    }
}
}

```

```

        while(a->right==true)
        {
            a=a->rightchild;

            if(a==th_head)
                break;

            cout<<a->data<<"\t";
        }
        a=a->rightchild;
    }
}

int main()
{
    ttree th;
    int n,e;
    cout<<"Enter no. of elements: ";
    cin>>n;
    cout<<"\nEnter elements: ";
    for(int i=0;i<n;i++)
    {
        cin>>e;
        th.insert(e);
    }

    cout<<"\n\n\tThreaded binary tree in inorder: ";
    th.inorder();
}

```

Output:

```
Enter no. of elements: 6
Enter elements: 7 9 12 15 6 11

..... Threaded binary tree in inorder: 6    7    9    11    12    15
.....
Process exited after 27.63 seconds with return value 0
Press any key to continue . . .
```

Conclusion : We successfully implement threaded binary tree and perform insertion and inorder traversal operation on it.

ASSIGNMENT NO.3.

Aim :-

There are flight paths between cities. If there is a flight between city A and city B then there is an edge between the cities. The cost of the edge can be the time that flight takes to reach city B from A, or the amount of fuel used for the journey. Represent this as a graph. The node can be represented by airport name or name of the city. Use adjacency list representation of the graph or use adjacency matrix representation of the graph. Justify the storage representations used .

Objective:- To learn adjacency list representation of graph.

Theory:-

Following two are the most commonly used representations of a graph.

1. Adjacency Matrix

2. Adjacency List

There are other representations also like, Incidence Matrix and Incidence List. The choice of the graph representation is situation specific. It totally depends on the type of operations to be performed and ease of use.

Adjacency Matrix:

Adjacency Matrix is a 2D array of size $V \times V$ where V is the number of vertices in a graph.

Let the 2D array be $adj[][]$, a slot $adj[i][j] = 1$ indicates that there is an edge from vertex i to vertex j . Adjacency matrix for undirected graph is always symmetric. Adjacency Matrix is also used to represent weighted graphs. If $adj[i][j] = w$, then there is an edge from vertex i to vertex j with weight w .

Adjacency List:

An array of lists is used. Size of the array is equal to the number of vertices. Let the array be $array[]$. An entry $array[i]$ represents the list of vertices adjacent to the i th vertex. This representation can also be used to represent a weighted graph. The weights of edges can be represented as lists of pairs. Following is adjacency list representation of the above graph.

Algorithm:-

1.BFS :-

- **Step 1:** SET STATUS = 1 (ready state)
for each node in G
- **Step 2:** Enqueue the starting node A
and set its STATUS = 2
(waiting state)
- **Step 3:** Repeat Steps 4 and 5 until
QUEUE is empty
- **Step 4:** Dequeue a node N . Process it
and set its STATUS = 3
(processed state).

- **Step 5:** Enqueue all the neighbours of N that are in the ready state (whose STATUS = 1) and set their STATUS = 2 (waiting state)
[END OF LOOP]
- **Step 6:** EXIT

2.DFS :-

- **Step 1:** SET STATUS = 1 (ready state) for each node in G
- **Step 2:** Push the starting node A on the stack and set its STATUS = 2 (waiting state)
- **Step 3:** Repeat Steps 4 and 5 until STACK is empty
- **Step 4:** Pop the top node N. Process it and set its STATUS = 3 (processed state)
- **Step 5:** Push on the stack all the neighbours of N that are in the ready state (whose STATUS = 1) and set their STATUS = 2 (waiting state)
[END OF LOOP]
- **Step 6:** EXIT

Program Code:-

```

Conclusion:- Thus,we have studied adjacency graph representation.

ASSIGNMENT NO.4.

Aim :- For a weighted graph G, find the minimum spanning tree using Prim's algorithm .

Objective:- To study the prim's algorithm.

Theory:-

Prim's algorithm is also a Greedy algorithm. It starts with an empty spanning tree. The idea is to maintain two sets of vertices. The first set contains the vertices already included in the MST, the other set contains the vertices not yet included. At every step, it considers all the edges that connect the two sets, and picks the minimum weight edge from these edges. After picking the edge, it moves the other endpoint of the edge to the set containing MST.

A group of edges that connects two set of vertices in a graph is called cut in graph theory. So, *at every step of Prim's algorithm, we find a cut (of two sets, one contains the vertices already included in MST and other contains rest of the verices), pick the minimum weight edge from the cut and include this vertex to MST Set (the set that contains already included vertices)*

Algorithm:-

- 1) Create a set *mstSet* that keeps track of vertices already included in MST.
- 2) Assign a key value to all vertices in the input graph. Initialize all key values as INFINITE. Assign key value as 0 for the first vertex so that it is picked first.
- 3) While *mstSet* doesn't include all vertices
 -a) Pick a vertex *u* which is not there in *mstSet* and has minimum key value.
 -b) Include *u* to *mstSet*.
 -c) Update key value of all adjacent vertices of *u*. To update the key values, iterate through all adjacent vertices. For every adjacent vertex *v*, if weight of edge *u-v* is less than the previous key value of *v*, update the key value as weight of *u-v*

The idea of using key values is to pick the minimum weight edge from cut. The key values are used only for vertices which are not yet included in MST, the key value for these vertices indicate the minimum weight edges connecting them to the set of vertices included in MST.

Program Code:-

```
#include<iostream>

#include<conio.h>

#include<stdlib.h>

using namespace std;

int cost[10][10],i,j,k,n,stk[10],top,v,visit[10],visited[10],u;

main()
{
    int m,c;
    cout <<"enter no of vertices";
    cin >> n;
    cout <<"enter no of edges";
    cin >> m;
    cout <<"\nEDGES Cost\n";
    for(k=1;k<=m;k++)
    {
        cin >>i>>j>>c;
        cost[i][j]=c;
    }
    for(i=1;i<=n;i++)
    for(j=1;j<=n;j++)
        if(cost[i][j]==0)
            cost[i][j]=31999;
```

```
cout <<"ORDER OF VISITED VERTICES";  
k=1;  
while(k<n)  
{  
    m=31999;  
    if(k==1)  
    {  
        for(i=1;i<=n;i++)  
            for(j=1;j<=m;j++)  
                if(cost[i][j]<m)  
                {  
                    m=cost[i][j];  
                    u=i;  
                }  
    }  
    else  
    {  
  
        for(j=n;j>=1;j--)  
            if(cost[v][j]<m && visited[j]!=1 && visit[j]!=1)  
            {  
                visit[j]=1;  
                stk[top]=j;  
                top++;  
            }  
    }  
}
```

```

Conclusion:- Thus,we have studied prims algorithm.

ASSIGNMENT NO.5.

Aim :-

You have a business with several offices; you want to lease phone lines to connect them up with each other; and the phone company charges different amounts of money to connect different pairs of cities. You want a set of lines that connects all your offices with a minimum total cost. Solve the problem by suggesting appropriate data structures .

Objective:- To study the use of kruskal's and prims algorithm in given problem.

Theory:-

What is Minimum Spanning Tree?

Given a connected and undirected graph, a *spanning tree* of that graph is a subgraph that is a tree and connects all the vertices together. A single graph can have many different spanning trees. A *minimum spanning tree (MST)* or minimum weight spanning tree for a weighted, connected and undirected graph is a spanning tree with weight less than or equal to the weight of every other spanning tree. The weight of a spanning tree is the sum of weights given to each edge of the spanning tree.

How many edges does a minimum spanning tree has?

A minimum spanning tree has $(V - 1)$ edges where V is the number of vertices in the given graph.

What are the applications of Minimum Spanning Tree?

See [this](#) for applications of MST.

Below are the steps for finding MST using Kruskal's algorithm

- 1. Sort all the edges in non-decreasing order of their weight.*
 - 2. Pick the smallest edge. Check if it forms a cycle with the spanning tree formed so far. If cycle is not formed, include this edge. Else, discard it.*
 - 3. Repeat step#2 until there are $(V-1)$ edges in the spanning tree.*
- The step#2 uses Union-Find algorithm to detect cycle.

The algorithm is a Greedy Algorithm. The Greedy Choice is to pick the smallest weight edge that does not cause a cycle in the MST constructed so far.

Algorithm:-

- create a forest F (a set of trees), where each vertex in the graph is a separate tree
- create a set S containing all the edges in the graph
- while S is nonempty and F is not yet spanning
 - remove an edge with minimum weight from S
 - if the removed edge connects two different trees then add it to the forest F , combining two trees into a single tree

At the termination of the algorithm, the forest forms a minimum spanning forest of the graph. If the graph is connected, the forest has a single component and forms a minimum spanning tree.

Program Code:-

Conclusion:- Thus,we have studied implementation of kruskal's algorithm.

ASSIGNMENT NO.6.

Aim :-

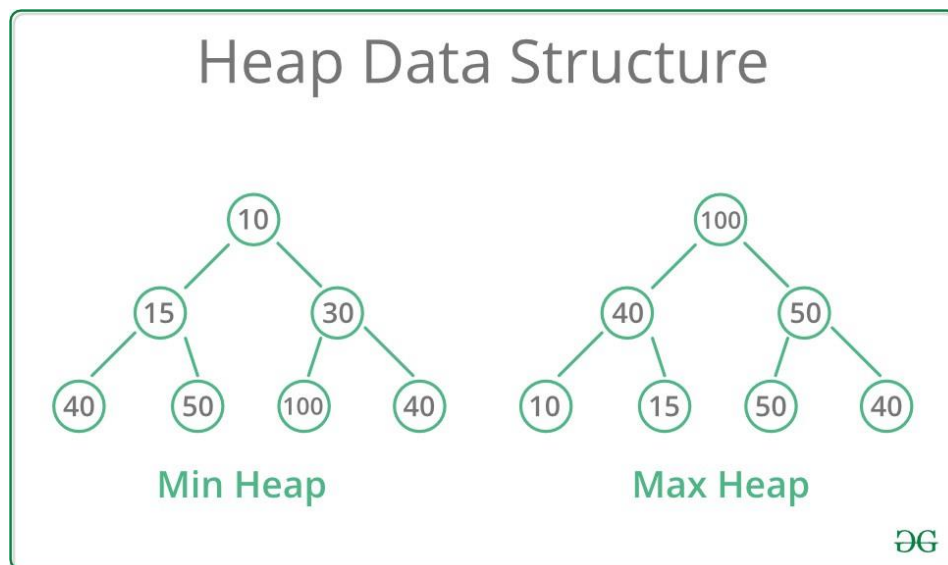

Read the marks obtained by students of second year in an online examination of particular subject. Find out maximum and minimum marks obtained in that subject using heap data structure.

Objective:- To study the heap data structure.

Theory:-

A Heap is a special Tree-based data structure in which the tree is a complete binary tree. Generally, Heaps can be of two types:

1. **Max-Heap:** In a Max-Heap the key present at the root node must be greatest among the keys present at all of it's children. The same property must be recursively true for all sub-trees in that Binary Tree.
2. **Min-Heap:** In a Min-Heap the key present at the root node must be minimum among the keys present at all of it's children. The same property must be recursively true for all sub-trees in that Binary Tree.

Applications:-

1. Heap sort.
2. Priority Queue.
3. Graph algorithm shortest path e.t.c.

Algorithm:-

1.max heap:-

Step 1 – Create a new node at the end of heap.

Step 2 – Assign new value to the node.

Step 3 – Compare the value of this child node with its parent.

Step 4 – If value of parent is less than child, then swap them.

Step 5 – Repeat step 3 & 4 until Heap property holds.

Program Code:-

```
#include<iostream>
```

```
using namespace std;
```

```
class hp
```

```
{
```

```
int heap[20],heap1[20],x,n1,i;
```

```
public:
```

```
hp()
```

```
{ heap[0]=0; heap1[0]=0;
```

```
}
```

```
void getdata();
```

```
void insert1(int heap[],int);
```

```

Conclusion:- Thus,we have studied heap data structure,

ASSIGNMENT NO.7.

Aim :- Insert the keys into a hash table of length m using open addressing using double hashing with $h(k)=1+(k \bmod (m-1))$.

Objective:- to study the hashing concept and its techniques.

Theory:-

Open Addressing

Like separate chaining, open addressing is a method for handling collisions. In Open Addressing, all elements are stored in the hash table itself. So at any point, size of the table must be greater than or equal to the total number of keys (Note that we can increase table size by copying old data if needed).

Insert(k): Keep probing until an empty slot is found. Once an empty slot is found, insert k.

Search(k): Keep probing until slot's key doesn't become equal to k or an empty slot is reached.

Delete(k): **Delete operation is interesting.** If we simply delete a key, then search may fail. So slots of deleted keys are marked specially as "deleted".

Insert can insert an item in a deleted slot, but the search doesn't stop at a deleted slot.

Open Addressing is done following ways:

a) Linear Probing: In linear probing, we linearly probe for next slot. For example, typical gap between two probes is 1 as taken in below example also.

let **hash(x)** be the slot index computed using hash function and **S** be the table size

If slot $\text{hash}(x) \% S$ is full, then we try $(\text{hash}(x) + 1) \% S$

If $(\text{hash}(x) + 1) \% S$ is also full, then we try $(\text{hash}(x) + 2) \% S$

If $(\text{hash}(x) + 2) \% S$ is also full, then we try $(\text{hash}(x) + 3) \% S$

Double Hashing:-

Double hashing is a collision resolving technique in **Open Addressed** Hash tables. Double hashing uses the idea of applying a second hash function to key when a collision occurs.

Double hashing can be done using :

$(\text{hash1}(\text{key}) + i * \text{hash2}(\text{key})) \% \text{TABLE_SIZE}$

Here $\text{hash1}()$ and $\text{hash2}()$ are hash functions and TABLE_SIZE is size of hash table.

(We repeat by increasing i when collision occurs)

First hash function is typically $\text{hash1}(\text{key}) = \text{key} \% \text{TABLE_SIZE}$

A popular second hash function is : **$\text{hash2}(\text{key}) = \text{PRIME} - (\text{key} \% \text{PRIME})$** where PRIME is a prime smaller than the TABLE_SIZE .

A good second Hash function is:

- It must never evaluate to zero
- Must make sure that all cells can be probed

Program Code:-

```
#include <bits/stdc++.h>
```

```
using namespace std;
```

```
#define TABLE_SIZE 13
```

```
#define PRIME 7
```

```
class DoubleHash
```

```
{
```

```
    int *hashTable;
```

```
    int curr_size;
```

```
public:
```

```
    bool isFull()
```

```
    {
```

```
        return (curr_size == TABLE_SIZE);
```

```
    }
```

```
    int hash1(int key)
```

```
    {
```

```
        return (key % TABLE_SIZE);
```

```
    }
```

```
    int hash2(int key)
```

```
    {
```

```
        return (PRIME - (key % PRIME));
```

```
}
```

```
DoubleHash()
```

```
{
```

```
    hashTable = new int[TABLE_SIZE];
```

```
    curr_size = 0;
```

```
    for (int i=0; i<TABLE_SIZE; i++)
```

```
        hashTable[i] = -1;
```

```
}
```

```
void insertHash(int key)
```

```
{
```

```
    if (isFull())
```

```
        return;
```

```
    int index = hash1(key);
```

```
    if (hashTable[index] != -1)
```

```
    {
```

```
        int index2 = hash2(key);
```

```
        int i = 1;
```

```
        while (1)
```

```
        {
```

```
        int newIndex = (index + i * index2) %  
            TABLE_SIZE;  
  
        if (hashTable[newIndex] == -1)  
        {  
            hashTable[newIndex] = key;  
            break;  
        }  
        i++;  
    }  
}  
  
else  
    hashTable[index] = key;  
    curr_size++;  
}  
  
// function to display the hash table  
void displayHash()  
{  
    for (int i = 0; i < TABLE_SIZE; i++)  
    {  
        if (hashTable[i] != -1)
```

```
        cout << i << " --> "

        << hashTable[i] << endl;

    else

        cout << i << endl;

    }

}

};

// Driver's code

int main()

{

    int a[] = {19, 27, 36, 10, 64};

    int n = sizeof(a)/sizeof(a[0]);

    cout<<"inserted elements in hash table are as follows:";

    // inserting keys into hash table

    DoubleHash h;

    for (int i = 0; i < n; i++)

        h.insertHash(a[i]);

    // display the hash Table

    h.displayHash();

    return 0;
```

}

Output Screenshots:-

```
inserted elements in hash table are as follows:0
1 --> 27
2 --> 10
3 --> 19
4 --> 36
5 --> 64
6 --> 10
7 --> 19
8 --> 36
9 --> 64
10 --> 10
11 --> 19
12 --> 36

Process exited after 0.01694 seconds with return value 0
Press any key to continue . . .

Compilation Time: 1.31s
```

Conclusion:- Thus, we have studied double hashing and hashing technique.

ASSIGNMENT NO.8.

Aim :- Department maintains a student information. The file contains roll number, name, division and address. Allow user to add, delete information of student. Display information of particular employee. If record of student does not exist an appropriate message is displayed. If it is, then the system displays the student

Objective:- To study the different data structure concepts to implement this program.

Theory:-

Input/output formatting

Writing to or reading from a file is similar to writing onto a terminal screen or reading from a keyboard. Differences are:

- File must be opened with an OPEN statement, in which the unit number and (optionally) the filename are given
- Subsequent writes (or reads) must refer to a known unit number (used for open)
- File should be closed at the end

File opening and closing

The syntax is:

```
OPEN([unit=]lunit,file='name' [,options])
```

```
CLOSE([unit=]lunit [,options])
```

For example:

```
OPEN(10, file='output.dat', status='new')
```

```
CLOSE(unit=10)
```

- The first parameter is the unit number and the keyword unit= can be omitted.
- The unit numbers 0,5 and 6 are predefined.
 - 0 is output for standard (system) error messages
 - 5 is for standard (user) input
 - 6 is for standard (user) output
 - These units are opened by default and should not be re-opened nor closed by users

Some options for opening a file:

- status: existence of the file ('old', 'new', 'replace', 'scratch', 'unknown')
- position: offset, where to start writing ('append')
- action: file operation mode ('write','read','readwrite')
- form: text or binary file ('formatted', 'unformatted')

- access: direct or sequential file access ('direct','sequential','stream')
- iostat: error indicator, (output) integer (non zero only upon an error)
- err: the label number to jump upon error
- recl: record length, (input) integer for direct access files only. Be careful, it can be in bytes or words...

Program Code:-

```
#include <iostream>
```

```
#include <fstream>
```

```
#include <cstring>
```

```
#include <iomanip>
```

```
#include <cstdlib>
```

```

Conclusion:- Thus, this assignment implemented successfully.

ASSIGNMENT NO.9.

Aim :- Company maintains employee information as employee ID, name, designation and salary. Allow user to add, delete information of employee. Display information of particular employee. If employee does not exist an appropriate message is displayed. If it is, then the system displays the employee details. Use index sequential file to maintain the data.

Objective:- to study use of different data structure concepts in this program.

Theory:-

Input/output formatting

Writing to or reading from a file is similar to writing onto a terminal screen or reading from a keyboard. Differences are:

- File must be opened with an OPEN statement, in which the unit number and (optionally) the filename are given
- Subsequent writes (or reads) must refer to a known unit number (used for open)

- File should be closed at the end

File opening and closing

The syntax is:

```
OPEN([unit=]lunit,file='name' [,options])
```

```
CLOSE([unit=]lunit [,options])
```

For example:

```
OPEN(10, file='output.dat', status='new')
```

```
CLOSE(unit=10)
```

- The first parameter is the unit number and the keyword unit= can be omitted.
- The unit numbers 0,5 and 6 are predefined.
 - 0 is output for standard (system) error messages
 - 5 is for standard (user) input
 - 6 is for standard (user) output
 - These units are opened by default and should not be re-opened nor closed by users

Some options for opening a file:

- status: existence of the file ('old', 'new', 'replace', 'scratch', 'unknown')
- position: offset, where to start writing ('append')
- action: file operation mode ('write','read','readwrite')
- form: text or binary file ('formatted', 'unformatted')
- access: direct or sequential file access ('direct','sequential','stream')
- iostat: error indicator, (output) integer (non zero only upon an error)
- err: the label number to jump upon error
- recl: record length, (input) integer for direct access files only. Be careful, it can be in bytes or words...

Program Code:-

```
#include <iostream>
```

```
#include <fstream>

#include <cstring>

#include <iomanip>

#include<cstdlib>

#define max 50

using namespace std;

class Employee
{
    char name[max];
    int empid;
    int sal;
    char de[50];
    friend class FileOperations;
public:    Employee()
        {
            strcpy(name,"");
            empid=sal==0;
            strcpy(de,"");
        }
    Employee(char name[max],int empid,int sal,char de[max])
    {
        strcpy(this->de,de);
        strcpy(this->name,name);
    }
}
```

```
        this->empid=empid;

        this->sal=sal;

    }

    int getEmpId()

    {

        return empid;

    }

    void displayEmployeeData()

    {

        cout<<endl<<empid<<"\t\t\t"<<name<<"\t\t\t"<<sal<<"\t\t\t"<<de;

    }

};

class FileOperations
